

Access: CurrentUser Function

In Access, the **CurrentUser** function returns the name of the current Access user. In a secured database, this would be the name of the user who has logged in. If the database is unsecured, this function would return Admin (the default account) as the name of the user.

The syntax for the **CurrentUser** function is:

CurrentUser()

VBA Code

The **CurrentUser** function can be used in VBA code. For example:

```
Dim LUser As String
```

```
LUser = CurrentUser()
```

In this example, the variable called LUser would now contain the name of the user currently logged into the Access database.

SQL/Queries

You can also use the **CurrentUser** function in a query.
